ABSTRACT

During 2009-2010, aphid parasitoid wasps (Hymenoptera: Braconidae: Aphidiinae) on stone fruit trees were investigated in Khorasan Razavi province, North East of Iran. In this survey, eight species from six genera, were reared from 26 associations (Aphid-host plant-parasitoid) in different localities in Khorasan Razavi province. *Aphidius transcaspicus* (62%) was the most abundant species of aphid parasitoids, in strict association with Hyalopterus spp. ITS2 rDNA sequence analyses confirmed classical studies. In phylogenetic analyses, our specimen, *A. transcaspicus* Mashhad1, made a single clade with other populations of this species. *A. transcaspicus* showed a good control potential on *Hyalopterus pruni* Geoffroy (Hom: Aphididae) on plum and apricot. So it can be used as a biocontrol agent against the mealy plum aphid in Khorasan Razavi geographical climates.

Key words: Aphidius transcaspicus, Hyalopterus pruni, ITS2, Iran.

INTRODUCTION

Aphidiinae are solitary obligatory endoparasitoids of aphids and many species of them have been considered as potential biocontrol agents (Stary 1970). The genera *Aphidius* Nees is one of the most diverse taxa within the subfamily Aphidiinae (Tomanovic *et al.*, 2007). In terms of systematics, *Aphidius* is a difficult genus (Mescheloff and Rosen, 1990).

In some species, aphid host knowledge is helpful in identification, some of the morphological characters used for identification may also vary (environmentallyinduced variations) (Pungerl, 1986). In *Aphidius transcaspicus*, geographical variability between populations of this species was indicated (Lozier *et al.*, 2009). There has been some uncertainty surrounding the taxonomic status of *Aphidius transcaspicus*. It was first described by Telenga (1958) from Uzbekistan. Stary (1975) considered *Aphidius transcaspicus* as synonymous with *Aphidius colemani* and again separated

from Aphidius colemani (Kavallieratos and Lykouressis, 1999). Despite the intense effort to separate species from each other, Uncertainties remain, because some of the morphological characteristics (maxillary and labial palps, body color, notaulices and wing venation), are very variable and overlap (Garantonakis et al., 2009). This Mediterranean parasitoid, treated in general papers, is specialized on *Hyalopterus* spp. (Takada, 1998; Kavallieratos et al., 2001; Rakhshani et al., 2008; Lozier et al., 2009) and Melanaphis donacis Passerini (Waterhouse, 1998; Kavallieratos et al., 2006). According to Stary (1965) and Lozier et al., (2008), it is an effective natural enemy of Hyalopterus pruni on peach. Erkin (1983), in studying natural enemies of aphids on stone and pome fruit trees in Turkey, found this species only on H. pruni. This species currently is under investigation as a potential biological control agent for the mealy plum aphid, Hyalopterus pruni, in prune trees in California (Lozier et al., 2008; Lathman and Mills, 2010). A. transcaspicus is a very common and economically important species in Iraq, which is climatically similar to Iran. It parasitizes H. pruni and Melanaphis donacis in mass number and was treated in relation to its biology and IPM proposals in Iraq (AI-Rawy et al., 1969). Use of parasitoid wasps as a biocontrol agents at first step requires correct identification (Lozier et al., 2006, 2008). Recently, DNA studies, using PCR techniques, have been investigated as a tool for identification and phylogeny (Landry et al. 1993). Ribosomal DNA has been an important target for these studies (Orrego and Agudelo Silva, 1993; Pinto et al., 1997). At the species and intraspecific levels, the internal transcribed spacer regions (ITS-1 and ITS-2) are often used as taxonomic tools in many groups of insects (Campbell et al., 1993). A region of these repeats more suitable for genus and species comparisons is the ITS2 region that site between the 5.8S and 28S RNA genes. The ITS2, a non-coding rapidly evolving region, has highly repetitive sequences that can differ among closely related populations, which have been proven useful for comparing closely related insect species, subspecies, or populations (Silva et al., 1999). In this survey, identification of A. transcaspicus as the most abundant aphid parasitoid that found especially on Hyalopterus pruni in apricot and plum trees in Khorasan Razavi province in North East of Iran was performed and phylogenetic analyses with other populations were studied.

MATERIAL AND METHODS

Collection and Deposition of Specimens

Sampling

Sampling on stone fruit trees was carried out during 2009 - 2010 in five different localities of Khorasan Razavi, Iran (Kardeh, Mashhad, Faragard, Golmakan, Torghabe). Samples from the host trees (almond, apricot, peach, plum) bearing aphid colonies consisting of live and mummified aphids and host plants were collected. Branches with leaves from each tree were carefully cut off and 15 branches with 8-10 cm were transported to plastic boxes which were labeled with date of sampling, host plants and location and covered with mesh for ventilation. Boxes were held at room temperature for 2-3 weeks till the adult parasitoids emerged. The emerged wasps were clipped daily using

an aspirator and dropped into 96% ethanol. Selected fresh specimens of aphids were immersed in 75% ethanol (Rezwani, 2001) and preserved there for later identification.

Specimen preparation

Phase contrast microscope

Emerged parasitoid preserved in 10% KOH along 48 hours for cleaning and dissected parasitoid specimens were mounted on slides in Hoyer for later identification. The external structures of emerged parasitoid (antennae, maxillary palps, labial palps, wings and female genitalia) were studied using an Olympus BH2 phase-contrast microscope and illustrated with a drawing tube. The ratio measurements were based on slide-mounted specimens. Terminology follows Kavallieratos *et al.* (2001) and Rakhshani et al. (2008).

Scanning electron microscope (SEM)

Emerged parasitoid left to soak overnight in 100% ethanol to remove any debris. The external structures (antennae, head, maxillary and labial palps, petiole and propodeum) were gold coated with a sputter coater and examined using a scanning electron microscope.

Molecular methods

DNA extraction and amplification

Genomic DNA was isolated from individual wasp by Qiagene kit (www. Qiagen. com). PCR amplification were performed by Primus thermocycler (MWGBiotech) in 25µl volumes including, 1µl DNA, 0.5µl dNTPs (CinaGen), 1µl Mgcl2 (CinaGen), 0.3µl *Taq* polymerase enzyme (100 units/µl) (CinaGen), 2.5µl PCR buffer (CinaGen), 1µl forward and reverse ITS2 primer (10pmol/µl) (Bioneer) and 16.5µl DWH20. The primers that used to amplify the ITS2 region were: 5-TGTGAACTGCAGGA-CACATG-3 (forward) and 5-GTCTTGCCTGCTCTGAG-3 (reverse) (Stouthamer *et al.*, 1999). The PCR cycling program was including 60s at 94°C followed by 30 cycles of 60s at 94°C, 90s at 50°C and 90s at 72°C with 8 min after the last cycle. 4µl PCR products and 1µl DNA Ladder (100bp) (Frementas) were electrophoresed on a 1% agarose gel. Finally gel was stained using ethidium bromide.

Molecular analyses

PCR product was sent to Milligene France Company for sequencing. Resulted sequence was edited and was confirmed as a ribosomal ITS2 by searching the GenBank database of the NCBI using blast protocol. Phylogenetic analyses were performed with similar sequences from GenBank (table1). Alignment of the sequences of the 5.8S, ITS2 and 28S regions was performed by ClustalW Program (Thompson *et al.*, 1994). MEGA Program version 4.0 (Tamura *et al.*, 2007) were used to estimate evolutionary distances and compute basic statistical quantities. Also maximum likelihood, maximum parsimony and neighbour joining trees from Aphidiinae and using *Alloxysta leunisii* (Hym: Figitidae: Charipinae) as the outgroup were constructed by MEGA 4.0 Program. To assess the support of clades in the phylogenic trees, the

bootstrap test was performed with 1000 replications (Felsenstein, 1985).

Table 1. Similar ITS2 sequences used for phylogenic studies.

RESULTS

Morphologic Study and Distribution

Morphology of Aphidius transcaspicus.

Female: Body length 1.7- 2.3 mm, light brown to yellowish., Head dark brown, the tentorial index is about 0.42, face and clypeus with sparse setae, maxillary palps with 4 palpomeres and labial palps with 3 palpomeres (Fig1A, B), Antennae filiform with 16-17 segments (Fig.1C), scape, pedicel and first flagellomere (F1) light brown, rest of flagellum dark brown, the length ratio of F1/F2 is 1.22 (Fig.1D), Metasoma brown, Petiole light yellowish brown with sparse setae in lower level (Fig.1E), Anterolateral area of petiole costate (Fig.1F), Propodeum carinated with 5 areolae, that central areola is narrow and pentagonal (Fig.1H), Forewing venation (incomplete): R1 vein not reaching forewing margin, stigma widely triangular, metacarpus about half of pterostigma length, Rs+M and 2/Rs veins absent, M and m-cu veins united forming M+m-cu vein (Fig.1I), Last terga light brown and ovipositor sheath dark brown (Fig.1J).

Male: Male is similar to the female except that its color is dark brown with black sparse spots and its antennae has 18-19 segments (Fig.1K).

Morphological and Molecular Methods in Identification of Aphidius transcaspicus Telenga

Molecular Study

Sequence data and divergence

The size of PCR product of *Aphidius transcaspicus* strain Mashhad1 on agarose gel closely was 700bp. Aligned sequence of 5.8S-ITS2-28S region is 553bp and ITS2 region is 384bp in length. Sequence is available from Gen Bank with HM536194 accession number. In distance matrix, *A. transcaspicus* AtM strain with 0.012 % divergence is mostly similar to *A. transcaspicus* At2G strain (Table 2).

Phylogenetic relationship

Trees obtained from neighbour joining and maximum likelihood analyses have similar topology to maximum parsimony analysis (neighbour joining data not shown)

(Fig. 2, 3). This indicates strong support for the clades. In description of maximum parsimony phylogram, all species and strains of *Aphidius* and *Lysiphlebus* formed a monophyletic group. Strains of *Aphidius colemani* and *Aphidius transcaspicus* were more closely related to each other than *Lysiphlebus species*. Within *Aphidius*, two clades were obvious. One with *A. transcaspicus* strains and the other containing *A. colemani* Viereck strains with 99% bootstrap value support (Fig. 2). *A. transcaspicus* Mashhad1 sited with other population of this species in a single clade. In alignment of the sequences data, insertion and deletion events as by turn transition and transversion happened which high similarity characters among *A. transcaspicus* strains were shown (Fig.4).

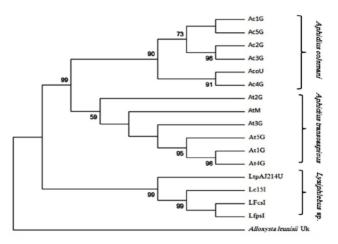

Fig. 2. Phylogenetic analysis of *Aphidius transcaspicus* and related species of this genus based on ITS2 sequence and maximum parsimony analysis, *Alloxysta leunisii* is as outgroup.

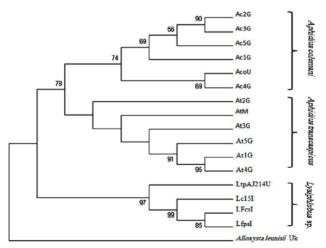

Fig. 3. Phylogenetic analysis of *Aphidius transcaspicus* and related species of this genus based on ITS2 sequence and maximum likelihood analysis, *Alloxysta leunisii* is as outgroup.

Table 2. ITS2 distance matrix (%) (above) and number of differences (below) on pairwise comparison among Aphidiinae population and Alloxysta leunisii as outgroup.

Fig. 4. Alignment of the sequences of the 5.8S, ITS2, and 28S regions of the Subfamily Aphidiinae.

DISCUSSION

In this survey the most abundant aphid was *Hyalopterus pruni* (Hom: Aphididae) and this species was also the most frequently parasitized. In the parasitoids, *Aphidius transcaspicus*, with 62%, was the most abundant parasitoid. This species showed a high biological potential to parasitize *Hyalopterus pruni* in Mashhad geographical climates. So it can be used as a biocontrol agent against the mealy plum aphid.

In molecular studies, The Aphidiinae population in comparison with *Alloxysta leunisii* (outgroup) are monophyletic. Phylogenetic studies on Aphidiinae, based on DNA sequence, show that this subfamily is monophyletic (Smith *et al.*, 1999; Sanchis *et al.*, 2000; Shi and Chen, 2005). *Lysiphlebus* species are separated from other Aphidiinae and located in a separated clade. Mackaur (1961) based on the morphological studies, considered *Lysiphlebus* as a member of subtribe Lysiphlebina within the tribe Aphidiini and *Aphidius* as a member of subtribe Aphidiina within the same tribe. Sanchis *et al.*, (2000), by studding 18S rDNA phylogeny, showed that Lysiphlebina is as a sister clade to Aphidiina. 16s rDNA Phylogeny (Chen *et al.* 2002) confirmed our result. Separation of *A. transcaspicus* and *A. colemani* from each other confirmed capacity of ITS2 region to separation species that morphologically are very similar. Analysis of the 5.8S, ITS2, and 28S regions show that *A. colemani* and *A. transcaspicus* populations are compatible and genetically very similar (Garantonakis *et al.* 2009).

ACKNOWLEDGEMENTS

We would like to thank Peter Stary (Institute of Entomology, Academy of Science of the Czech Republic) for identification of parasitoid wasps. Also, we express thanks to David Vogeltin and Doris Lagos (Department of Crop Sciences, National Soybean Research Center, University of Illinois, Urbana, USA) for identification of host aphids.
