ABSTRACT
A factorial experiment base on randomized complete block design with three replications carried out to investigate the effect of salicylic acid at enhancing stress tolerance in petunia plants during 1392. Factors were two petunia varieties (Sonja pink and an Iranian variety), two irrigation levels (70 and 40 percent of FC) and three salicylic acid doses (0, 1 and 2 mM). There were significant differences between varieties in response to different irrigation levels and salicylic acid doses. Flower number per plant, flower diameter, leaf area, shoot and root dry weight, biomass, chlorophyll content, stomatal conductance decreased by higher drought level. Electrolyte leakage enhanced by drought stress. Destructive effects of drought stress on petunia, reduced by applying salicylic acid reduced. Morphological and ornamental characteristics of flowers improved by higher doses of salicylic acid. Electrolyte leakage decreased using 2 mM of salicylic acid. Results showed that drought tolerance decreased by salicylic acid in both varieties. Best results gained by applying 2 mM of salicylic acid.

Keywords: *Drought Stress, Biomass, Salicylic Acid, Electrolyte Leakage, Stomatal Conductance*

INTRODUCTION
High quality water resources are limit in arid and semi-arid areas of the world. Mean precipitation of Iran is about 252 mm which is one third of global precipitation mean. Water deficit is one of the most important limiting factors in crop cultivation in Iran and drought stress is inevitable during plant growth season (Khodabande and Jalilian, 1997). Petunia is an annual ornamental plant belongs to Solanaceae family which originated in South America (Khalighi, 1997). Petunia is widely planted in urban landscape and it is necessary to control its water consumption by improving its drought resistance. Plants response to environmental stresses is different and depends on stress intensity and duration and time of stress occurrence (Bohnert and Jensen, 1996) and plant spices and growth stage (Mirfatah *et al.*, 2008; Sanchez *et al.*, 1998). Plants have different mechanisms to reduce stress effects. Water deficit results in lower plant growth and yield due to lower photosynthesis rate and leaf area (Miranzade and Emam, 2010). Cell membrane stability known as an indicator of drought tolerance in plants. Leaf relative water content is an appropriate measure of plant water status in terms of the physiological consequence of cellular water deficit and electrolyte leakage (EL) is another indicator of cell injuries during drought stress (Foker *et al.*, 1998; Fu *et al.*, 2004). Osmoregulation is one of drought resistance mechanisms of plants (Izadi *et al.*, 2009). Applying exogenous compounds is one way to reduce destructive effects of abiotic stresses (Yuan *et al.*, 2008). Salicylic acid (SA) is a messenger molecule which plays a non-enzymatic anti-oxidant role in regulating plant physiological mechanisms during stress occurrence (Arfan *et al.*, 2007). Fresh and dry weight of root and shoot, stem diameter and leaves number of cucumber plant increased by spraying salicylic acid (Yildirim *et al.*, 2008). Samia *et al.*, (2009) reported that oxidative stress reduced by applying 0.15 mg of exogenous salicylic acid at saline condition. Soaking seeds and leaf spray of seedlings of melon by 0.1-1 mM acetyl salicylic acid reduced injury effects of drought stress in treated plants (Korkmaz *et al.*, 2007). Shoot growth of barley (Pancheva, 1996) and wheat (Shakirova, 2007), root length and lignin accumulation in cell walls of soya bean increased using salicylic acid (Al-Hakimi, 2008). Petunia is commonly panted in arid and semi-arid regions of Iran as a landscape plant,

thus the experiment was conducted to investigate the effect of applying salicylic acid on petunia growth and ornamental characteristics in order to enhancing plant tolerance to drought condition.

MATERIALS AND METHODS

Seeds of two varieties of *Petunia hybrida* planted in trays which filled with coco peat at 2013 growing season. The experimental site located at 59°35´ E and 36°17´ N. Studied varieties were Sonja pink and Iranian variety of petunia. Coco peat had an acidity in the range of pH 5.8 to 6.5 and EC in range between 0.75 to 1.25 dS/m. Germination temperature of laboratory was between 24-29 °C (Vall, 2004). Seedlings moved to pots with 12 cm diameter, at 7-8 leaves stage. Pots filled with 1 loam: 1 sand: 1 leaf mold mixture. A factorial experiment base on randomized complete block design with three replication was carried out. Factors were two petunia varieties (Sonja pink and an Iranian variety), two irrigation levels (70 and 40 percent of FC) and three salicylic acid doses (2, 1 and 2 mM). The first salicylic acid (SA) treatment applied 45 days after transferring of seedlings to pots. This was the beginning of productive phase of plants. Leaves sprayed each 10 days, with salicylic acid until two sides of leaf completely wetted. Drought stress applied base on field capacity in each treatment.

Each pot weighted by a digital scale every day and water added up to determined level (base weight loss of each pot). Day and night temperature of greenhouse adjusted at 25 and 18°C with 65% relative humidity. Plants were treated for 30 days. At the end of 30 days ornamental characteristics of plants measured. Measured traits were: flower number in each plant, flower diameter, corolla tube, plant height, main and secondary shoots counted in 10 plants and average of the numbers subjected to analysis of variance. Root and shoot samples oven dried at 72°C for 48 hours for determining dry weight. Flower diameter and corolla tube measured using Callipers. Plant height measured applying ruler.

Leaf area measured using and leaf area meter (Li-Cor, Model Li-1300, USA). Chlorophyll content measured five time in each treatment by SPAD 502, Minolta, Japan. Stomatal conductivity determined with porometer device.

Electrolyte leakage estimated in five samples of each treatment using following equation (Lutts *et al.*, 1996):

$$EL = [(EL0/EL1) \times 100]\%$$

While EC0 and EC1 refers to primary and secondary electrical conductivity and EL refers to electrolyte leakage. At the end of growing time, pots emptied and fresh shoot and root weight measured by digital scale. Then samples oven dried at 72 °C for 48 hours and dry weight measured for each sample.

Data were analyzed applying JMP8 software. Comparison of means carried out using LSD test at 5% probability level.

RESULTS AND DISCUSSION

Results

Analysis of variance showed that all measured traits (except for electrolyte leakage) significantly affected by variety, irrigation level and salicylic acid doses ($p<0.01$) (table 1). All measured traits affected by interaction between variety and irrigation level. All measured traits except for chlorophyll content, EL and branch number significantly affected by interaction between variety and SA. All flower characteristics except for flower diameter, plant height and main and secondary shoots affected by interaction between irrigation level and salicylic acid dose. Interaction between variety, irrigation level and SA dose was significant in respect of flower number per plant, corolla tube, leaf area and root dry weight ($p<0.01$) (table 1).

Comparison between means showed that Sonja pink had higher amounts in all measured characteristics compare with Iranian variety (table 2). All plant characteristics decreased by 40% FC compare with 70% FC water level (table 2).

Research Article

Flower diameter, flower diameter, corolla tube, chlorophyll content, plant height, leaf area, root and shoot dry weight, biomass, stomatal conductivity and main and secondary shoots increased by applying 2 mM salicylic acid compare with 0 and 1 mM doses (table 2). The lowest and highest electrolyte leakage observed by 2 and 0 mM salicylic acid respectively. There was no significant difference between applying 1 and 2 mM of salicylic acid in respect of root dry weight, biomass and primary and secondary shoot number (table 2).

The highest and lowest flower number and diameter belonged to Sonja pink at 70% Fc and Iranian variety at 40% FC correspondingly. The highest and lowest corolla tube, chlorophyll content, plant height, leaf area, root and shoot dry weight, biomass and primary and secondary shoots number belonged to Iranian variety at 70% FC and Sonja pink at 40% FC respectively. The highest and lowest electrolyte leakage observed in Iranian variety at 40%FC and Sonja pink at 70% FC respectively (table 3).

The highest and lowest flower number and diameter produced by Sonja pink which sprayed with 2mM salicylic acid and Iranian variety with zero mM salicylic acid (table 3). The highest corolla tube, chlorophyll content, plant height, leaf area, root and shoot dry weight and biomass, stomatal conductivity, primary and secondary shoots produced by Iranian variety and 2 mM salicylic acid while the lowest belonged to Sonja pink and zero level of salicylic acid. The highest and lowest electrolyte leakage observed for Sonja pink with zero level of salicylic acid and Iranian variety with 2mM salicylic acid (table 3).

The highest and lowest flower number and diameter, corolla tube and chlorophyll content, plant height, leaf area, root and shoot dry weight, biomass, stomatal conductivity and primary and secondary shoots belonged to 70%FC and 2 mM salicylic acid and40% FC and zero dose of salicylic acid respectively.

The highest and lowest EL observed for 40% FC with zero dose of SA and 70% FC and 2 mM SA correspondingly (table 3). The highest and lowest flower number and diameter produced by Sonja pink at 70% FC and 2 mM SA, and Iranian variety at 40% FC and 0 mM SA (figure 1 and 2).

The highest and lowest corolla tube, chlorophyll content, plant height, leaf area, root and shoot dry weight and biomass, primary and secondary shoot number belonged to Iranian variety at 70% FC and 2 mM SA and Sonja pink at 40%FC and 0 mM SA (table 4, figure 3). The highest and lowest EL observed in Iranian variety at 40% FC and 0 mM SA and Sonja pink at 70% FC and 2 mM SA correspondingly (figure 4).

Discussions

Different varieties showed different responses to drought stress and applying of SA as expressed at results. Comparing these two varieties is hard due to their inherent differences in morphological and ornamental traits. But the lower EL of Iranian variety at drought condition showed its higher cell membrane stability compare with Sonja pink. In both varieties, drought results in lower amount of measured characteristics. EL of both varieties increased by 40% FC compare with 70% FC. Cell membrane is the first part of cells which injure by drought stress (Inze and Van Montague, 1995). Drought stress result in oxidative stress which enhances reactive oxygen species production and storage in plant cells. Thus cell walls fatty acids oxidation occurs and cell wall stability will loss ((Inze and Montague, 1995).

Leaf area and shoot dry weight decreased by drought stress. Drought results in lower cell growth and decreases cell production by meristems (Tradieu *et al.*, 2000). Low leaf area results in low photosynthesis rate. Dry material production is directly depending to photosynthesis rate. Thus lower amount of leaf area will result in lower dry material accumulation in plants (Porwanto, 2003). Stomatal conductivity reduced by drought in both varieties. Drought stress results in abscisic acid (ABA) increase in leaves. ABA stimulates the closure of stomata in order to reduce water loss (Abdul *et al.*, 2009). Flower number and diameter and corolla tube decreased by drought stress which were in agreement with Bayat *et al.*, (2010).

All petunia characteristics improved and EL decreased, using SA in both irrigation levels. Other researchers reported the same results on cucumber (Bayat *et al.*, 2012), melon (Korkmaz *et al.*, 2007), tomato and bean (Senaranta *et al.*, 1999). Applying SA enhances accumulation of polyamines like putrescine, spermine and spermidine in plants. Higher amount of polyamines results in higher cell membrane stability (Nemeth *et al.*, 2002). In this experiment, applying SA resulted in higher chlorophyll content at drought condition. The same results reported in cucumber (Bayat *et al.*, 2012). SA prohibits auxin and cytokinin loss in plants and thus enhances cell division and plant growth. SA keeps photosynthetic aspects like chlorophyll content, at proper level and thus help plants to well growth and develop (Hayat *et al.*, 2010).

Morphological characteristics like leaf area, plant height, root and shoot dry weight, biomass, flower number and diameter and primary and secondary shoot numbers enhanced by applying SA compare with 0 mM SA, at drought condition. At drought condition, leaf number of violet and gloxinia enhanced by 10% using SA (Martin-Mexand and Larqué-Saavedra, 2001). Applying foliar spray of SA resulted in higher root and shoot fresh weight, root and shoot dry weight, stem diameter and leaf number of cucumber (Yildirim *et al.*, 2008) and maize (Khodary *et al.*, 2004) at salinity. Stem diameter, biomass,

plant height and leaves number of cucumber enhanced using SA at drought condition (Bayat *et al.,* 2012). SA regulate plant growth and cell division via other hormones like auxin, cytokinin, gibberellin and ABA. SA results in higher cell division in meristems and enhances root length (Shakirova *et al.,* 2003). Salicylic acid controls photosynthesis system, photosynthesis amount, pigment content and stomatal conductivity and regulates these procedures for appropriate growth and development (Popova *et al.,* 2009, Steven *et al.,* 2006, El-Tayeb, 2005, Kormkaz *et al.,* 2007).

Conclusion

Results showed that morphological and ornamental characteristics of both varieties affected by drought significantly. Applying salicylic acid improved measured traits at drought condition. Iranian variety showed higher resistance to drought compare with Sonja pink. In both varieties the highest drought resistance observed by applying 2 mM salicylic acid.
