Effect of Nitrogen Fertilizer on Biological Parameters of the Cowpea Aphid and Associated Productivity Losses in Common Globe Amaranth

A. Hosseini¹, M. Hosseini¹*, M. Goldani², J. Karimi¹, and H. Madadi³

ABSTRACT

Reducing nitrogen status of floriculture plants is an effective tactic in pest management by decreasing host plant quality. Life table parameters and population growth rate of *Aphis craccivora*, as well as cosmetic and qualitative parameters losses associated with aphid infestation were evaluated in relation to N fertilization levels on *Gomphrena globosa*, under greenhouse condition. Four N fertilization levels (0, 30, 60, and 100% of recommended 2 kg m⁻³) were used. The results indicated that aphid’s intrinsic rate of natural increase on plants fertilized with 100% of the recommended N level was the highest. Abundance and population growth rate of aphid also positively correlated with N fertilization levels. The interactive effect of aphid population and N fertility significantly affected growth parameters of the plants. In the absence of aphid, plant yield improved linearly with increasing N levels. However, aphid population highly decreased shoot to root ratio and the number of flowers in plants fertilized with 100% of the recommended N level. According to our findings, fine-tuning fertility to reduce *A. craccivora* population is a steadfast tactic to produce marketable globe amaranth ornamental plant.

Keywords: Aphid performance, *Aphis craccivora*, Nitrogen fertilization, Plant yield, Population growth.

INTRODUCTION

*Gomphrena globosa* L. (Amarantaceae), the common globe amaranth, is a popular ornamental plant grown as cut flower, annual beds, border and potted flowering plants in mild-climate regions (Dinda *et al.*, 2006). This ornamental plant has relatively few pests (Bachman, 2011), among which the cowpea aphid, *Aphis craccivora* Koch (Hemiptera: Aphididae), is a serious one (Lovisolo and Conti, 1966; Jones, 1967; Tao, 1990). This aphid causes plant growth stunting, deformed leaves, and delay in initiation of flowering by feeding phloem sap and transmission of viral diseases. Even in heavy attack, it can cause plant death (Obopile, 2006). In consequence, cosmetic parameters of ornamental plants such as *G. globosa* devalue and crop yield reduction (Byrne *et al.*, 1990; Alfonsina, 2008).

Nutritional quality of plant plays a significant role in host plant-herbivore interactions (Mattson, 1980; White, 1993; Trdan *et al.*, 2005; Trdan *et al.*, 2008). The most critical macronutrient, which profoundly influences the growth and fecundity of herbivorous insects, is nitrogen (Mc Neill and Southwood, 1978; Douglas, 2006). Probably, one important reason for...
this phenomenon is the vast differences in N compound concentration between herbivorous insects (6-10%) and plant tissues (1.5–3%) (Mattson, 1980; Elser et al., 2000). Scarcity of N compounds is especially true for phloem-feeding insects (e.g. aphids) because of the low N content of phloem (0.004-0.06%) compared to other plant tissues (Minkenberg and Fredrix, 1989; Ponder et al., 2000). One of the cultural practices of ornamental plants that is commonly applied to improve their commercial and aesthetic aspects is N fertilization (N) (Elliott et al., 2004; Chau et al., 2005). However, N fertility, with increasing amino acid and nitrate level in host plant (Mengel and Kirkby, 2001) can enhance nutritional quality and attractiveness of plants for herbivorous insects; therefore, it improves performance parameters of phloem feeders (Mattson, 1980; White, 1993; Douglas, 2006; Fallahpour et al., 2015). For instance, results of a study conducted by Aqueel and Leather (2011) showed that 0.4 g plant\(^{-1}\) N fertilizer in the form of ammonium nitrate significantly enhanced the fecundity and longevity of *Sitobion avenae* (F.) and *Rhopalosiphum padi* (L.) in comparison to those by 0.1 g plant\(^{-1}\) N fertilizer level. Zehnder and Hunter (2008) also found an increase in per capita population growth of *Aphis nerii* Boyer de Fonscolombe on *Asclepias tuberosa* L., i.e. plants with application of N fertilization in the form of ammonium nitrate.

Thus, based on previous reports, lowering N fertilization level, which may reduce yield and quality of ornamental plants a little, could be a useful management tactic to decrease pest population and control costs (Chau et al., 2005; Chow et al., 2011). In the north and northeast of Iran, *G. globosa* plants have been produced as a popular floriculture crop (Ghasemi and Kafi, 2007). The results of earlier studies indicated that the nursery of this plant needed a high N fertilization regime due to its fast-growing and highly-demanding nutrition (Huang et al., 2002; Benary, 2011) so as to increase their susceptibility to damage caused by aphid infestation. Thus, N fertilizer usage should be optimized to a level that markedly maintains physiological status of plant optimum and aesthetic parameters whilst minimizing the aphid population growth.

In this study, the specific objectives were to: (1) Assess the effect of N fertilization levels on life table parameters of the cowpea aphid on *G. globosa* plants, (2) Evaluate the effect of N fertilization on aphid population growth rate and the associated amaranth plants productivity (e.g. number of flower buds) and quality losses (e.g. nitrogen-compounds status of leaf) under greenhouse conditions.

**MATERIALS AND METHODS**

**Host Plant, Fertilization and Aphid Population**

Sixty four seedlings (7 cm in height) of the common globe amaranth were transplanted into separated plastic pots (23×17 cm, height×diameter) on July 5\(^{th}\), 2011. The pots were filled with 3 kg substrate including perlite (Mehr Parsian Exir Company, Iran), sphagnum peat moss (Kuomari Coir Products, Singapore), and sandy soil (ratio 1:1:1 v/v) as a growing media (Huang et al., 2002). The seedlings were irrigated two times daily for 4 weeks with distilled water. One month after transplanting, the seedlings (17 cm in height) were subsequently assigned to different N treatments until the end of experiments. The recommended N level for the periodic feeding (thrice weekly for two months) of potted amaranth plants is approximately 2 kg m\(^{-3}\) (as slow release N fertilizer) (Benary, 2011). The volume of amaranth plant pot was 7.6×10\(^{3}\) m\(^{3}\), so the recommended level of N fertilization per pot was calculated at 12 g. Based on N fertilizer (Urea, CO (NH\(_2\)) \(_2\) as source of nitrogen), four different N treatments including 0, 30, 60, and 100% of the recommended N level
(12 g), were applied. The amounts of phosphorous (P) (trisodium phosphate as source of phosphorous) and potassium (K) (potassium sulfate as source of potassium) in all N fertilization treatments were equal to 10 g (52 g trisodium phosphate) and 20 g (44 g potassium sulfate), respectively. These amounts were separately given to the units three times for two weeks, starting with N application. The plants received recommended nutrient (N, P, K) solution (100 ml), and, in the intervals between fertilizers applications, were tap watered. All plants were kept at 26±1°C, 65±5% RH and a light: dark regime of 16 L:8 D hour. The study was terminated on October 30th, 2011.

Aphids used in this study were procured from an A. craccivora colony, originally established with individuals collected from bean, Phaseolus vulgaris L., grown in a research greenhouse at the College of Agriculture of Ferdowsi University of Mashhad, Iran. The aphids were grown on vegetative G. globosa plants within net-covered cages (60×70 cm, height×diameter) for 53 days. The cages were kept in a growth chamber at 26±1°C, 65±5% RH and a light: dark regime of 16 L:8 D hour. Effects of N fertilization Levels on Life Table Parameters of A. craccivora

To determine the performance of A. craccivora on amaranth plants fertilized with different N regimes, life table parameters of aphid were considered as trial 1. Eight amaranth plants were assigned to each of the four N fertilization treatments. In each N fertilization treatment, 35 adult aphids from the reared colony were placed individually on the surface of young expanded plant leaves (90 days old) using camel’s hair brush. A ventilated clip cage (1.5 cm² in diameter) encaged each individual aphid. After 24 hours, adults and all the youngs, except one first instar, were removed. This single aphid was allowed to develop to adulthood. All aphids were checked daily from the onset of reproduction and every other day thereafter. The number of young nymphs produced by each aphid (age-specific fecundity) was also recorded daily and then removed during the remainder of its life. This trial was done in a growth chamber at 26±1°C, 65±5% RH, and 16:8 hour (L: D) photoperiod. To construct the age-specific fertility life table, age specific survival rate (lₓ) and average aphids progeny in x age class (mₓ) were obtained. Based on these data, the intrinsic rate of natural increase (rₓ, female progeny per female per day) was estimated using the following equation (Birch, 1948):

\[ \sum L_x m_x e^{-r_x \text{pivotal} x} = 1 \]  

Where, Lₓ and pivotal x are \((l_x + l_{x+1})/2\) and \([x + (x + 1)/2]\), respectively. Other parameters of fertility life table including net reproduction rate \(R_0 = \sum \Sigma m_x\), Doubling Time \(DT = (\ln 2)/r_m\), mean generation time \(T = (\ln R_0)/r_m\) and finite rate of increase \(\lambda = e^{rm}\) were likewise computed (Carey, 1993). To find the differences in \(R_0, T, DT, \lambda\) and \(r_m\) values, Jackknife method was applied for producing pseudo-values (Meyer et al., 1986; Maia et al., 2000).

To assess the impact of different N fertilization levels on the aphid performance, the life table parameters of A. craccivora, except aphid nymphal survivorship which was analyzed with non-parametric Kruskal-Wallis test, were subjected to one-way ANOVA (SAS Institute Inc. 2003). Accordingly, if significant differences between means were detected (\(P \leq 0.05\), Fisher’s Protected LSD test was used. Before ANOVA, the normality of the data was tested by Kolmogrov-Smirnov in Minitab software (Minitab 16 statistical software). Assumption of the homogeneity of data was tested through Bartlett’s test in the same software.

Effect of N Fertilization Levels on Aphid Population Growth Rate

This experiment was a completely randomized design (4×2 full factorial) with
the four levels of fertilization (0, 30, 60, and 100% of the recommended N level) crossed with two levels of aphid densities (12 individuals of A. craccivora or no aphids) as trial 2. The experimental unit consisted of an individual amaranth plant enclosed in a 70×30 cm (height×diameter), cylindrical-shaped clear plastic container topped with an organy-mesh cover. Eight units were used for each of the four N fertilization treatments. Half of the units per treatment were randomly selected and inoculated with aphids when the plants were 13 weeks old (60 days after the plants were assigned to the treatments). To approach a stable age distribution and allow the population to grow exponentially from the start of the experiment (Vehrs et al. 1992), variously-aged aphids (four adults, 4 L 3-4, 4 L 1-2) were transferred, using a camel’s hair brush, to the apical region of the plant in each unit. To assess the effect of aphid infestation on yield losses and cosmetic parameters of amaranth plants, the other 4 units were kept free of aphids. Aphid infested (AI) and non-infested (non-AI) plants were grown in two growth chambers (26±2°C, 65±10% RH, 16 L: 8 D hour) to avoid aphid’s contamination. Both growth chambers had the same environmental conditions.

Fifteen days later, equivalent to approximate 4×(multiplication) the doubling time of A. craccivora, the total number of aphids was counted visually in each unit of N treatments and population growth rate (r) of aphid was estimated using the following formula (Hosseini et al., 2010a):

$$ r = \frac{\ln(N_{x+1} / N_x)}{t} $$

Where, $N_x$ is the population size at time $x$, $N_{x+1}$ the population size at time $x+1$ and $t$ the difference in days between time $x+1$ and $x$.

One-way ANOVA was applied to analyze the effect of fertilization levels on the overall population growth rate of the aphid. Whenever a significant result for the ANOVA was obtained (P≤ 0.05), Fisher’s Protected LSD test was performed to determine the significance of differences between means.

**Effect of N Fertilization Levels on G. globosa Growth Parameters**

At the termination of trial 2, net photosynthesis, stomatal conductivity, leaf chlorophyll content, leaf area, flower and bud number, and plant height as well as dry weight of shoot (total plant top), root, leaf and central stem of amaranth plant were measured to characterize yield of plant in AI and non-AI units.

Net photosynthesis rate ($P_n$) and stomatal conductivity ($g_s$) were taken between 8:00 and 9:00 a.m. in each fertilization treatment using portable photosynthesis system (LI-COR Inc., Lincoln, NE, USA) and leaf porometer system (Sc-1), respectively. In both measurements, three new expanded leaves from each pot (either AI or non-AI pot) were randomly selected. There were 6 replications per treatment combination (n= 6).

Leaf chlorophyll content was obtained with a SPAD portable leaf chlorophyll meter (SPAD-502, Minolta Camera, Co. Japan). Each leaf was one replication, and there were three replications per treatment combination (n= 3). During the study, $P_n$, $g_s$ and leaf chlorophyll content were measured once a week, but only the last data were reported.

For measuring shoot dry matter (equal to leaf and central stem DM) and root in each pot, total top plant (whole aerial shoot of the plant) and root were harvested and lightly washed with deionized water. Then, the leaves, central stem and root of harvested plants were detached and separately oven-dried for 48 hours at 70°C and weighed by a digital balance (Sartorius GD503, Germany, sensitivity 1mg) to obtain shoot dry matter.

The acquired data was analyzed using a two-way factorial ANOVA to assess the effect of interaction between N fertilization levels and aphid presence. Significant
Nitrogen Fertilizer Effect on Aphid Performance

RESULTS

Effects of N Fertilization Levels on Life Table Parameters of *A. craccivora*

Aphid nymphal Developmental Time and Survivorship

Nymphal developmental time of *Aphis craccivora* was not influenced by N fertilization levels (F<sub>3, 79</sub> = 0.7, P > 0.05, Table 1). Likewise, no significant N treatment effect was observed for aphid juvenile survivorship (H = 1.6, P > 0.05, Table 1).

Aphid Adult Longevity and Reproduction

The applied N fertilization levels did not have any significant effect on aphid adult longevity (F<sub>3, 76</sub> = 1.08, P > 0.05, Table 1). The highest number of offspring per adult aphid (12.4±1.1) was acquired on the plants fertilized with 100% recommended N level and the lowest number (7.9±1.2) was observed on the plants not fertilized (F<sub>3,76</sub>= 2.68, P<0.05, Table 1).

Age-Specific Fertility Life Table Parameters

Aphids feeding on the plants that received the greatest N level (12 g) had the highest *rₚ* and the lowest value was observed in aphid...
reared on non-N-fertilized plants (0) ($F_{3,74}=2.48$, $P<0.05$, Table 1). Likewise, the net reproductive rate ($R_0$) and finite rate of increase ($\lambda$) of *A. craccivora* positively grew by increasing N fertilization levels ($R_0$: $F_{3,74}=9.31$, $P<0.05$; $\lambda$: $F_{3,74}=11.87$, $P<0.05$, Table 1). Aphids reared on plants with 100% recommended N level had the shortest doubling time ($D_T$: $F_{3,74}=13.64$, $P<0.05$). However, N fertilization levels did not have any significant effect on aphid generation time ($T$) ($F_{3,74}=0.72$, $P>0.05$, Table 1).

**Effect of N Fertilization Levels on Aphid Population and Quality Losses of *G. globosa* Plants**

Results of linear regression analysis revealed that the growth population rate ($r$) of *A. craccivora* grew along with increasing N fertilization levels to reach a maximum level ($0.141\pm0.006$) for aphids reared on amaranth plants fertilized with 100% recommended N level ($F_{3,12}=6.05$, $P<0.05$, $Y=0.004 X+0.9$, $P<0.05$, $R^2=0.58$).

*A. craccivora* infestation significantly reduced both vegetative and reproductive growth parameters of AI plants. $P_n$ and $g_s$ were the highest in non-AI plants, fertilized with 60% of the recommended N level, while they were lowest in AI plants fertilized with 100% recommended N [$P_n$: $F_{3,47}=8.19$, $P<0.05$, $g_s$: $F_{3,47}=5.85$, $P<0.05$; Figure 1 (A and B)].

There was a significant interactive effect of N fertilization levels and aphid presence on chlorophyll content of leaves ($F_{3,23}=3.68$, $P<0.05$). Chlorophyll content did not have a significant difference among N fertilized plants (Figure 1-C). However, in non-fertilized treatment, there was a significant fall in chlorophyll content of both AI and non-AI plants.

In the 100% N recommended fertilized non-AI plants, root Dry Matter (DM) was markedly lower than that in other treatment combinations ($F_{3,23}=9.76$, $P<0.01$, Table 2). In the highest N (100%) received non-AI plants, central stem DM increased...
Nitrogen Fertilizer Effect on Aphid Performance

Table 2. Effect of N fertilization levels and Aphis craccivora abundance on Carbon:Nitrogen ratio (C:N), Nitrogen (N) content (%), Shoot:Root ratio (Dry Matter g DM) Number (No.) of flower, shoot:root DM (mean±SD), Leaf-N content (% of recommended N level) and C:N ratio in non-AI plants fertilized with 60% or 100% N-recommended level. Significant differences are indicated by letters a to c, where a indicates significantly lower C:N content than b and c. (F1,23= 5.03, P< 0.05, Table 2). Leaf DM in non-AI plants fed either with 60 or 100% N reached the highest level (F1, 23= 52.70, P< 0.01, Table 2). The number of flowers and shoot to root ratio were significantly different in treatment combinations (Number of flower: F3, 23= 16.06, P< 0.01; Shoot to root ratio: F3, 23= 48.02, P< 0.01), and those were highest in non-AI plants fertilized with 100% N recommended level (Table 2).

The regression analyses confirmed a major positive relationship between N fertilization level and both the number of flowers and shoot to root ratio in the absence of aphid [Shoot to root ratio (A): Y= 0.11X+5.4, P< 0.01, R² = 0.75; Number of flowers (B): Y= 0.48X+47.9, P< 0.01, R² = 0.77]. Nevertheless, in the presence of aphid, these relationships were less strong than in the absence of aphid, both regarding shoot to root ratio (Y= 0.02X+6.4, P< 0.05, R² = 0.45) and the number of flowers (Y= 0.31X+44.9, P< 0.01, R² = 0.88).

Leaf-N content was at its peak in non-AI plants fertilized with either 60% or 100% of the recommended N level in comparison with the other treatment combinations (N: F1,35= 6.89, P< 0.05; C/N: F1,35= 11.76, P< 0.05, Table 2). In addition, in non-fertilized plants, leaf-N content markedly decreased. The highest C/N ratio was obtained in non-AI plants with no fertility; whereas the lowest C/N ratio was found in both non-AI and AI plants fertilized with either 60% or 100% of the recommended N level (Table 2).

**DISCUSSION**

Based on evidence in the literature, N fertilization of ornamental plants generally leads to increased growth rate and higher potential fecundity of insect herbivores and, ultimately, to increased population densities (Bentz and Larew, 1992; Davies et al., 2004; Hogendorp et al., 2006; Chow et al., 2011). The results of the present study also confirmed that some life table parameters, such as the
intrinsic rate of increase ($r_m$) of *A. craccivora* positively correlated with the application of N fertilization in *G. globosa* plants. Nevertheless, since there was not a significant difference of developmental time of *A. craccivora* on plants’ receiving various amounts of N fertilization, aphids’ $r_m$ was only affected by its fecundity rate. In other words, greater aphid fecundity by increasing N application resulted in higher $r_m$ of aphids. Namely, according to Jauset et al. (2000), lower egg mortality, larger nymphs and females, and higher oviposition frequencies of *T. vaporariorum* result from over-fertilization of the host plant. The $r_m$ of the whiteflies that developed on tomato plants fertilized with the highest nitrogen level was about 14% higher (no significance was found) than that of whiteflies that developed on plants supplied with the lowest nitrogen level. Besides, Khan and Port (2008) reported that while higher N fertilization levels did not significantly affect maturation time of *Rhopalosiphum padi* (L.) on *Triticum aestivum* L., aphids’ $r_m$ was increased in aphid fecundity on plants receiving higher N fertilization levels. Therefore, it seems that fecundity of insect herbivore is the most important determinant of population growth in the context of fertilizer effects (Stafford et al., 2012).

Population size of *A. craccivora* responded well to N fertilization levels on amaranth plants. Chow et al. (2009) similarly reported that the density of *Tetranychus urticae* Koch on the cut roses was affected by N fertilization and enhanced with increasing N level (from 15 to 150 ppm). High population density of *B. tabaci* adult and immature instars on tomato were related to fertilization by 205 mg L$^{-1}$ N and 335 mg L$^{-1}$ (Žanić et al., 2011). Moreover, the population growth of *A. gossypii* was at its highest on cucumber at the greatest N level (190 ppm) (Hosseini et al., 2010a).

In general, the better the growth rate is, the higher the population density of *A. craccivora* is correlated with the highest N content, in plants fertilized with 100% of the recommended N level. Dietary N, which is an important factor in aphid development and growth, fundamentally exists in the forms of amino acids in phloem (Douglas, 2006). Therefore, increasing N in plant tissues with N fertilization may enhance total amino acid concentration in phloem, thus, aphids have a greater supply of nutritional elements (White, 1993; Bentz et al., 1995). On the other hand, increasing N fertilization decreased the $C/N$ ratio of amaranth plants phloem tissue, and probably their carbon-based secondary compounds, including flavonoid (Ferrerres et al., 2011), saponin and coumarine (Rufino Arcanjo et al., 2011), and sterol glucoside compounds (Dinda et al., 2006). Therefore, reduced levels of defensive metabolites of *G. globosa* plants induced by higher N content might have contributed to the better performance and population increase of *A. craccivora*. Yet, concentrations of carbon-based secondary metabolites of amaranth plants under different N regimes were not evaluated in the current study. Therefore, the possibility of this hypothesis would be addressed in future research.

The plant phenotypic plasticity is the ability of morphological modification in response to the biotic and abiotic stimulants (Valladares et al., 2007; Žanić et al., 2013). The biotic effect of aphids infestation on host plant and the abiotic response to high N fertilization led to changes in growth parameters of plants (Valladares et al., 2007). In this study, vegetative (shoot to root ratio), and reproductive (flower number) yield, as well as physiological status of amaranth plants were greatly affected by N fertilization levels and aphid presence.

In the presence of aphid, the associated productivity losses of *G. globosa* plants which received the highest N fertilization was more than those of plants which were fed with lower N fertilization levels. For instance, the number of flowers in the plants with 100% of the recommended N fertilization showed greater loss (c.a 22%) than that in the plants receiving 60% N (c.a 5%). In addition, the higher loss of shoot to root ratio (c.a 59%) was acquired in the plants grown on 100% N level than that in plants grown with 60% N level (18%). The highest productivity losses of infested plants fertilized with 100 % N may be attributed to
their lowest net photosynthesis rate ($P_n$) (Figure 1). Indeed, higher aphid population at higher N fertilization level could decrease $P_n$ by feeding on sap phloem N content in which the lower amount of N element was allocated to plants $P_n$ (Davies et al., 2004). Similar to our result, Hosseini et al. (2010a) reported that at the highest N fertilization level (190 ppm), A. gossypii induced the greatest yield reduction of cucumber plants, which is probably related to a significant decrease in net photosynthesis rate.

G. globosa is an ornamental plant used as a bed in public locations or cut flower; therefore, it is critical to be grown in a way that supports lower risks of insecticide applications. In floriculture crops, reduction of fertilization could be considered as an effective tactic in pest management, if altered fertilization regimes can reduce pest populations with little loss in crop yield (Chow et al., 2009; 2011). Our results have demonstrated that lowering N fertilization in amaranth plants with 60% of recommended N significantly decreased A. craccivora population without substantial loss of flower yield and marketability. Then, a proper application of N fertilization could be used for reducing A. craccivora populations. Consequently, growers would benefit from application of less insecticides. Moreover, reduction in the amount of N application has additional advantages such as reducing floriculture production costs and chemical run-off. Finally, we suggest that future studies should evaluate the effectiveness of reduction in fertilization as a relatively simple and easily implemented tactic with other IPM strategies, including biological control (Hosseini et al., 2010b), and cultural practices (Stavisky et al., 2002) for A. craccivora management on amaranth plants and other ornamental crops.

چکیده

از روش‌های مؤثر در مدیریت آفات، افت کلیه گیاه میزان از طریق کاهش سطح تغذیه‌ی نیتروزن می‌تواند بهبود یابد. در این پژوهش، توافقات زیستی و نرخ رشد جمعیت شته ایفیخا تحت Aphis craccivora Koch باشد. در این پژوهش، توافقات زیستی و نرخ رشد جمعیت شته ایفیخا تحت Aphis craccivora Koch متفاوت می‌باشد. در این پژوهش، توافقات زیستی و نرخ رشد جمعیت شته ایفیخا تحت Aphis craccivora Koch متفاوت می‌باشد. در این پژوهش، توافقات زیستی و نرخ رشد جمعیت شته ایفیخا تحت Aphis craccivora Koch متفاوت می‌باشد. در این پژوهش، توافقات زیستی و نرخ رشد جمعیت شته ایفیخا تحت Aphis craccivora Koch متفاوت می‌باشد. در این پژوهش، توافقات زیستی و نرخ رشد جمعیت شته ایفیخا تحت Aphis craccivora Koch متفاوت می‌باشد. در این پژوهش، توافقات زیستی و نرخ رشد جمعیت شته ایفیخا تحت Aphis craccivora Koch متفاوت می‌باشد. در این پژوهش، توافقات زیستی و نرخ رشد جمعیت شته ایفیخا تحت Aphis craccivora Koch متفاوت می‌باشد. در این پژوهش، توافقات زیستی و نرخ رشد جمعیت شته ایفیخا تحت Aphis craccivora Koch متفاوت می‌باشد. در این پژوهش، توافقات زیستی و نرخ رشد جمعیت شته ایفیخا تحت Aphis craccivora Koch متفاوت می‌باشد. در این پژوهش، توافقات زیستی و نرخ رشد جمعیت شته ایفیخا تحت Aphis craccivora Koch متفاوت می‌باشد. در این پژوهش، توافقات زیستی و نرخ رشد جمعیت شته ایفیخا تحت Aphis craccivora Koch متفاوت می‌باشد. در این پژوهش، توافقات زیستی و نرخ رشد جمعیت شته ایفیخا تحت Aphis craccivora Koch متفاوت می‌باشد. در این پژوهش، توافقات زیستی و نرخ رشد جمعیت شته ایفیخا تحت Aphis craccivora Koch متفاوت می‌باشد. در این پژوهش، توافقات زیستی و نرخ رشد جمعیت شته ایفیخا تحت Aphis craccivora Koch متفاوت می‌باشد. در این پژوهش، توافقات زیستی و نرخ رشد جمعیت شته ایفیخا تحت Aphis craccivora Koch متفاوت می‌باشد. در این پژوهش، توافقات زیستی و نرخ رشد جمعیت شته ایفیخا تحت Aphis craccivora Koch متفاوت می‌باشد. در این پژوهش، توافقات زیستی و نرخ رشد جمعیت شته ایفیخا تحت Aphis craccivora Koch متفاوت می‌باشد. در این پژوهش، توافقات زیستی و نرخ رشد جمعیت شته ایفیخا تحت Aphis craccivora Koch متفاوت می‌باشد. در این پژوهش، توافقات زیستی و نرخ رشد جمعیت شته ایفیخا تحت Aphis craccivora Koch متفاوت می‌باشد. در این پژوهش، توافقات زیستی و نرخ رشد جمعیت شته ایفیخا تحت Aphis craccivora Koch متفاوت می‌باشد. در این پژوهش، توافقات زیستی و نرخ رشد جمعیت شته ایفیخا تحت Aphis craccivora Koch متفاوت می‌باشد. در این پژوهش، توافقات زیستی و نرخ رشد جمعیت شته ایفیخا تحت Aphis craccivora Koch متفاوت می‌باشد. در این پژوهش، توافقات زیستی و نرخ رشد جمعیت شته ایفیخا تحت Aphis craccivora Koch متفاوت می‌باشد. در این پژوهش، توافقات زیستی و نرخ رشد جمعیت شته ایفیخا تحت Aphis craccivora Koch متفاوت می‌باشد. در این پژوهش، توافقات زیستی و نرخ رشد جمعیت شته ایفیخا تحت Aphis craccivora Koch متفاوت می‌باشد. در این پژوهش، توافقات زیستی و نرخ رشد جمعیت شته ایفیخا تحت Aphis craccivora Koch متفاوت می‌باشد. در این پژوهش، توافقات زیستی و نرخ رشد جمعیت شته ایفیخا تحت Aphis craccivora Koch متفاوت می‌باشد. در این پژوهش، توافقات زیستی و نرخ رشد جمعیت شته ایفیخا تحت Aphis craccivora Koch متفاوت می‌باشد. در این پژوهش، توافقات زیستی و نرخ رشد جمعیت شته ایفیخا تحت Aphis craccivora Koch متفاوت می‌باشد. در این پژوهش، توافقات زیستی و نرخ رشد جمعیت شته ایفیخا تحت Aphis craccivora Koch متفاوت می‌باشد. در این پژوهش، توافقات زیستی و نرخ رشد جمعیت شته ایفیخا تحت Aphis craccivora Koch متفاوت می‌باشد. در این پژوهش، توافقات زیستی و نرخ رشد جمعیت شته ایفیخا تحت Aphis craccivora Koch متفاوت می‌باشد. در این پژوهش، توافقات زیستی و نرخ رشد جمعیت شته ایفیخا تحت Aphis craccivora Koch متفاوت می‌باشد. در این پژوهش، توافقات زیستی و نرخ رشد جمعیت شته ایفیخا تحت Aphis craccivora Koch متفاوت می‌باشد. در این پژوهش، توافقات زیستی و نرخ رشد جمعیت شته ایفیخا تحت Aphis craccivora Koch متفاوت می‌باشد. در این پژوهش، توافقات زیستی و نرخ رشد جمعیت شته ایفیخا تحت Aphis craccivora Koch متفاوت می‌باشد. در این پژوهش، توافقات زیستی و نرخ رشد جمعیت شته ایفیخا تحت Aphis craccivora Koch متفاوت می‌باشد. در این پژوهش، توافقات زیستی و نرخ رشد جمعیت شته ایفیخا تحت Aphis craccivora Koch متفاوت می‌باشد. در این پژوهش، توافقات زیستی و نرخ رشد جمعیت شته ایفیخا تحت Aphis craccivora Koch متفاوت می‌باشد. در این پژوهش، توافقات زیستی و نرخ رشد جمعیت شته ایفیخا تحت Aphis craccivora Koch متفاوت می‌باشد. در این پژوهش، توافقات زیستی و نرخ Rhet foyer معنی داری افزایش جمعیت شته در بالاترین سطح کوددهی (400 درصد سطح کوددهی) محیطی معنی‌داری افزایش یافته. همچنین، فروامی و نرخ رشد جمعیت شته با کوددهی نیتروزن همبستگی منابع داد. برهمکنش حضور شته و کوددهی بر عملکرد گیاه میزان تأثیری معنی‌داری داشت. در شرایط عدم حضور شته، عملکرد گیاه با افزایش سطح کوددهی نیتروزن بهطور معنی‌داری افزایش یافته. با این وجود، در بالاترین سطح توصیه شده کوددهی (100 درصد) جمعیت شته، تعداد گل ها و نسبت زیست توده اندام هواپی با ریشه و شدت کاهش داد. براساس نتایج مطالعه حاضر، اعمال کوددهی بهینه بهعنوان تاکتیک مدیریتی کارآمد در کنترل اینویه جمعیت شته ایفیخا روی گیاه زیستی گل تکه ای توصیه می‌گردد.
